

## SPECIFICATION

# DEVICE FOR DETECTING THREE-DIMENSIONAL SHAPES OF ELONGATED FLEXIBLE BODY

## BACKGROUND OF THE INVENTION

## Field of the Art

8 This invention relates to a device for detecting three-dimensional  
9 (3D) shapes and conditions of an elongated flexible body, for example,  
10 3D shapes and conditions of bends in an endoscopic flexible insertion  
11 tube which has been introduced into a body cavity of a patient.

Prior Art

13 For instance, in the case of an endoscope for examination of  
14 lower digestive ducts, its insertion tube needs to be inserted into  
15 through a complicate path of insertion which contains three-  
16 dimensional bends, more specifically, through the intestinum rectum,  
17 sigmoid colon, and lower, transverse and ascending colons. Besides,  
18 the path of insertion is not always maintained in stable conditions and  
19 can easily change into different conditions upon application of an

1 external force. Therefore, as the insertion tube is inserted along a  
2 path of insertion, in some cases the fore leading end of the insertion  
3 tube is pushed against an intracavitory wall portion and stuck on that  
4 intracavitory wall portion failing to advance to farther target points. In  
5 this manner, great difficulties are often experienced in operating the  
6 insertion tube of an endoscope along a path of insertion, and the  
7 insertion of the endoscopic insertion tube can impose an extremely  
8 great burden on the part of the patient unless it is operated with  
9 meticulous skill.

10 In consideration of the foregoing situations, various attempts  
11 have thus far been made to the development of a device which can  
12 three-dimensionally grip the shape of an endoscopic flexible insertion  
13 tube which has been introduced into a body cavity. It has been  
14 known, for example, from Japanese Laid-Open Patent Application H5-  
15 91972, to employ a pair of fiber optics having obliquely cut end faces  
16 connected at a predetermined open angle relative to each other,  
17 detecting conditions of a bend in the insertion tube by calculating the  
18 open angle between the end faces of the two fiber optics.

19 Further, it has been known, for example, from Japanese Laid-

1 Open Patent Application 2002-131009, to detect a three-dimensional  
2 shape of an endoscopic biopsy channel by the use of four sense coils  
3 each consisting of four single-core coils and capable of detecting a  
4 magnetic field in the same direction and on the same straight line.  
5 The four sense coils are located at four equidistant spatial positions on  
6 an orbit around a bed on which a patient lies, while, for example, 16  
7 source coils which are adapted to produce different high frequency  
8 drive signals are provided on a probe to be introduced into a body  
9 cavity of the patient through a biopsy channel within an insertion tube  
10 of an endoscope. In this case, coordinates of spatial positions of the  
11 respective source coils are calculated on the basis of magnetic field  
12 data of the source coils to detect the three-dimensional shape of the  
13 endoscopic biopsy channel in which the probe has been inserted, that  
14 is to say, to detect the three-dimensional shape of the insertion tube of  
15 the endoscope.

16 In this connection, in a case where spliced fiber optics couples  
17 are used in the manner as in the firstly mentioned prior art Japanese  
18 Laid-Open Patent Application H5-91972, four fiber optics couples are  
19 required to detect the shape of a bent portion at a certain position of

1 an endoscopic insertion tube, necessitating to locate four fiber optics  
2 couples at intervals along the length of the endoscopic insertion tube.  
3 Therefore, in order to enhance resolution over the distance in the  
4 longitudinal direction of the insertion tube, namely, in order to  
5 increase the detection points along the length of the insertion tube, it  
6 becomes necessary to provide an extremely large number of fiber  
7 optics couples at short intervals along the length of the endoscopic  
8 insertion tube. On the other hand, in the case of secondly mentioned  
9 prior art Japanese Laid-Open Patent Application 2002-131009, it is an  
10 essential requisite to provide a bed with sense coils for detection of a  
11 3D shape of the endoscopic insertion tube, which requires to make  
12 adjustments of a patient's lying position relative to the sense coils in  
13 addition to complicate signal processing operations.

## SUMMARY OF THE INVENTION

15 In view of the foregoing situations, it is an object of the present  
16 invention to provide a device which is simplified and compact in  
17 construction but capable of detecting three-dimensional shapes of an  
18 elongated flexible body like a flexible insertion tube of an endoscope  
19 without necessitating complicate signal processing.

1           In accordance with the present invention, in order to achieve the  
2       above-stated objective, there is provided a device for detecting three-  
3       dimensional shapes of an elongated flexible body, which comprises: a  
4       sensor cable adapted to be inserted into an axial coextensive passage  
5       within an elongated flexible body, the sensor cable having two pairs of  
6       fiber Bragg grating strands each having a plural number of refractive  
7       index change portions periodically in a predetermined pitch; a light  
8       source connectible to each one of the fiber Bragg grating strands to  
9       input a light beam containing a Bragg wavelength to the refractive  
10      index change portions; and a signal processor adapted to receive  
11      reflection diffraction light signals from the refractive index change  
12      portions of each fiber Bragg grating strand, and to detect a three-  
13      dimensional shape of the elongated flexible body by measuring strains  
14      of the refractive index change portions on the basis of shifts of the  
15      reflection diffraction light signals from a reference wavelength.

16           Fiber Bragg grating (hereinafter referred to as "FGB" for brevity)  
17       is an optical fiber device having refractive index change portions in a  
18       core portion. When a light beam of a specific wavelength is input to  
19       the optical fiber, reflection diffraction light is produced at each

1 refractive index change portion. The light of the specific wavelength is  
2 called "Bragg wavelength." The wavelength of the reflection diffraction  
3 light change when the refractive index change portions are strained.  
4 The greater the straining, the greater becomes the shift in wavelength.  
5 It follows that wavelength of reflection diffraction light from the  
6 refractive index change portions changes when a strand of FBG is  
7 bent. That is to say, the angle of bend in the FBG strand can be  
8 detected on the basis of shifts in wavelength of reflection diffraction  
9 light signals from the respective refractive index change portions.

10 In a preferred form of the present invention, a sensor cable is  
11 constituted by two pairs of FBG strands each having a plural number  
12 of refractive index change portions formed in a core portion  
13 periodically in a predetermined pitch. In this instance, the sensor  
14 cable is used by placing same in an axial passage which is formed  
15 coextensively through an elongated flexible body. Let alone flexibility,  
16 the sectional shape of the sensor cable depends on the sectional shape  
17 of the passage in which it is to be placed. In case the passage is non-  
18 circular in shape, e.g, square or oval, it is desirable to form the sensor  
19 cable in a corresponding shape. For instance, the sectional shape is

1       circular in the case of a biopsy channel which is provided within a  
2       flexible insertion tube of an endoscope, so that the pairs of FBG  
3       strands of the sensor cable are accommodated in a tubular carrier  
4       casing which is correspondingly circular shape in section. In the  
5       sectional area of the sensor cable, the two pairs of FBG strands are  
6       located on X- and Y-axes which intersect perpendicularly with each  
7       other at the center of the sensor cable. In this case, one pair of FBG  
8       strands are located on X-axis while the other pair are located on Y-  
9       axis. However, the provision of the perpendicularly intersecting X-  
10      and Y-axes is not necessarily an imperative requisite. In this  
11      connection, it is desirable that the refractive index change portions in  
12      each one of the FBG strands be located in the same or substantially  
13      the same position in the sectional area of the sensor cable. However, if  
14      desired, one pair of FBG may be located in a deviated position relative  
15      to the other pair of FBG.

16           The refractive index change portions which are formed  
17      periodically in a predetermined pitch in each one of the FBG strands  
18      of the sensor cable may have the same index of refraction. Otherwise,  
19      refractive index change portions with different indices of refraction

1 may be arranged in the axial direction of the sensor cable. However,  
2 the refractive index change portions which are located in the same  
3 coordinate position in the sectional area of the sensor cable should  
4 have the same index of refraction. A variation in index of refraction  
5 relative to the core portion of the fiber results in a corresponding  
6 variation in Bragg wavelength.

7 In case different refractive index change portion are provided in  
8 FBG, reflected light from each refractive index change portion contains  
9 information with regard to the degree of bending and the position of  
10 FBG. Further, the bending direction of the FBG sensor cable can be  
11 detected from reference signals in various Bragg wavelengths and the  
12 amounts of shift from respective wavelengths. Accordingly, on the  
13 basis of the reflection diffraction light signal from the respective  
14 refractive index change portions of FBG, it is possible to detect in what  
15 direction and to what extent the sensor cable is bent. For this  
16 purpose, the light beam to be input to FBG from a light source should  
17 contain respective Bragg wavelengths. Namely, the light source should  
18 be arranged to project a composite light beam of the respective  
19 wavelength or to sweep the respective wavelengths one after another.

1           In a case where FBG is provided with a plural number of  
2       refractive index change portions all having the same index of  
3       refraction, it becomes necessary to detect the positions of the  
4       respective refractive index change portions. To this end, for example,  
5       the positions of the respective refractive index change portions can be  
6       detected by the use of an interferometer. More specifically, for this  
7       purpose, one may use an interferometer using an incident light from a  
8       light source as reference light and matching the length of light path of  
9       the reference light with that of reflection diffraction light from each  
10      one of the refractive index change portions for measurement of  
11      interference. Therefore, in this case, it is desirable to employ a light  
12      source which is arranged to project a low coherence light beam, for  
13      measuring interference one after another for each one of the refractive  
14      index change portions.

15           The FBG sensor cable is applicable to an elongated flexible body  
16      which has an internal coextensive axial passage to place the sensor  
17      cable in. In use, the elongated flexible body is inserted into an  
18      internal cavity and invisible from outside like a flexible insertion tube  
19      of an endoscope. More specifically, in case the sensor cable is to be

placed in an endoscopic biopsy channel for detection of three-dimensional shapes of a flexible insertion tube of an endoscope, it is desirable for the sensor cable to have an outside diameter close to the inside diameter of the biopsy channel, as long as placement of the sensor cable is not hindered by tightness.

**BRIEF DESCRIPTION OF THE DRAWINGS**

7 In the accompanying drawings:

8 Fig. 1 is a schematic illustration explanatory of the construction  
9 of refractive index change portions of a fiber Bragg grating (FBG)  
10 strand employed in the present invention;

11 Fig. 2 is a schematic illustration explanatory of the construction  
12 of the fiber Bragg grating strand as a whole:

17 detecting three-dimensional shapes of the sensor cable according to a  
18 second embodiment of the present invention.

19 DESCRIPTION OF PREFERRED EMBODIMENTS

1           Hereafter, the present invention is described more particularly  
2       by way of its preferred embodiments with reference to the  
3       accompanying drawings. Referring first to Fig. 1, there is  
4       schematically shown the construction of a FBG strand. In Fig. 1,  
5       indicated at 1a is a cladding portion and at 1b is a core portion of a  
6       FBG strand 1. The FBG strand 1 is formed by inserting the core  
7       portion 1b in the cladding portion 1a. The FBG strand 1 is provided  
8       with refractive index change portions 2 in its core portion 1b, where  
9       the index of refraction is varied. At the refractive index change  
10      portions 2, the index of refraction is changed periodically over a  
11      predetermined length which corresponds to an ultimate sensor length.  
12      When light of Bragg wavelengths is incident on this FBG strand,  
13      reflection diffraction light signals are obtained from the reflective index  
14      change portions 2. As the fiber is bent from a straight reference state,  
15      the refractive index portions 2 are strained and as a result the length  
16      of the sensor is varied. Elongation of the sensor length causes the  
17      reflection diffraction light a shift to a longer wavelength from a  
18      wavelength in the reference state. When the sensor length is  
19      shortened, it causes the reflection diffraction light a shift to a shorter

1 wavelength. The amount of the shift in wavelength which occurs to the  
2 reflection diffraction light varies depending upon the degree of the  
3 straining of the refractive index change portions 2.

4 In this connection, as shown in Fig. 2, a plural number of  
5 refractive index change portions 2a, 2b, 2c, ..... 2n are provided  
6 periodically in a predetermined pitch P. In a case where these  
7 refractive index change portions 2a, 2b, 2c, .... 2n are arranged to have  
8 different refractive indices from each other, the reflection diffraction  
9 light is obtained from the respective varied refractive index sections at  
10 different Bragg wavelengths  $\lambda_1, \lambda_2, \lambda_3, \dots, \lambda_n$  as shown in Fig. 3.

11 Accordingly, in case a light signal which contains the wavelength  
12 ranges  $\lambda_1$  to  $\lambda_n$  is fed into four FBG strands 1 from a light source 3,  
13 reflection diffraction light components of wavelengths  $\lambda_1, \lambda_2, \lambda_3, \dots, \lambda_n$   
14 are obtained from the refractive index change portions 2a, 2b, 2c, ....  
15 2n, respectively. These reflection diffraction light components contain  
16 signals indicative of positions of bends in the longitudinal direction of  
17 the FBG strands 1 along with direction and degree of the bending.

18 As shown in Figs. 4 and 5, four FBG strands 1, with the  
19 properties as described above, are located on or in positions in the

1 proximity of the circumference of a round flexible columnar or  
2 cylindrical carrier casing 4 of rubber or soft synthetic resin material at  
3 intervals of 90 degrees from each other. In this case, as shown in Fig.  
4 5, there is obtained a sensor cable 5 having two pairs of FBG strands  
5 on two perpendicularly intersecting axes X and Y, namely, a first pair  
6 of FBG strands 1a and FBG 1b (a fiber couple on Y-axis) and a second  
7 pair of FBG strands 1c and 1d (a fiber couple on X-axis) with angular  
8 intervals of 180 degrees from each other. In the axial direction of the  
9 sensor cable 5, refractive index change portions 2a, 2b, 2c, .... 2n of  
10 the respective FBG strands 1a to 1d are located on the same sectional  
11 planes. The sensor cable 5 is disconnectably connectible to a control  
12 unit 8 with a light source 3, coupler 6 and signal processor 7 built in  
13 its housing.

14 Within the housing of the control unit 8, signal light from the  
15 light source 3 is divided by a coupler 6 and fed to the respective FBG  
16 strands 1a to 1d, and reflection diffraction light signals from the  
17 respective varied refractive index sections are fed to the signal  
18 processor 7 and thereby processed through predetermined signal  
19 processing operations. As a consequence, when the sensor cable 5 is

1       bent at some point, it is possible to detect at what position, in what  
2       direction and to what extent the sensor cable 5 is bent, that is to say,  
3       it becomes possible to recognize the three-dimensional shape of the  
4       sensor cable. If desired, a light circulator may be used in place of the  
5       coupler 6.

6           In use, the above-described sensor cable 5 is placed in a passage  
7       or channel within an elongated flexible member to detect three-  
8       dimensional shapes of the elongated flexible member. As for example  
9       of the elongated flexible member, an elongated flexible insertion tube  
10      12 of an endoscope 10 is shown in Figs. 6 and 7. The flexible insertion  
11      tube 12 is extended out from and connected to a manipulating head  
12      assembly 11 of the endoscope 10. A major part of the insertion tube  
13      12 consists of a flexible body section 12a which can be bent in  
14      arbitrary bending directions at the time of the insertion tube is  
15      introduced into a body cavity through a bent path of insertion. An  
16      angle section 12b and a rigid tip end section 12c are successively  
17      connected to the fore end of the flexible body section 12a. The angle  
18      section 12b can be angularly bent by remote control to turn the rigid  
19      tip end section into a desired direction. For operating the angle

1 section 12b, an angulation knob 13 is mounted on the manipulating  
2 head assembly 11 as an angulation control means.

3 As well known in the art, an endoscopic observation mechanism,  
4 including illumination windows 14 and an endoscopic observation  
5 window 15, is mounted on the rigid tip end section 12c of the insertion  
6 tube 12. More particularly, an entrance way 17 to a biopsy channel is  
7 provided in the vicinity of the proximal end of the insertion tube 12  
8 which is connected to the manipulating head assembly 11. On the  
9 other hand, an exit way 18 of the biopsy channel is opened in a casing  
10 of the rigid tip end section 12c in the vicinity of the above-mentioned  
11 endoscopic observation mechanism. The biopsy channel 16 is  
12 constituted by a flexible tube with sufficient flexibility in bending  
13 directions, and extended through the endoscopic insertion tube 12 in  
14 such a way as to connect the entrance way 17 with the exit way 18.  
15 The sensor cable 5 is placed in the biopsy channel 16 for detection of  
16 three-dimensional shapes of the endoscopic insertion tube 12 within a  
17 body cavity. In this connection, in order to detect three-dimensional  
18 shapes of the insertion tube 12 accurately, it is desirable to minimize  
19 the diametric differential between the outside diameter of the sensor

1       cable 5 and the inside diameter of the endoscopic biopsy channel 16  
2       within a range which would not hinder insertion of the sensor cable 5.

3           In the foregoing description, the flexible insertion tube 12 of the  
4       endoscope 10 is shown as an object in measuring three-dimensional  
5       shapes of an elongated flexible member according to the method of the  
6       present invention. Above all, it is important to detect three-  
7       dimensional shapes of a flexible insertion tube of a colonoscope which  
8       is usually required to inch the insertion tube toward a target  
9       intracavitory site of interest through a path of insertion containing  
10      bends of complicate shapes which can easily be turned into different  
11      shapes by application of external forces. The recognition of three-  
12      dimensional shapes is extremely advantageous from the standpoint of  
13      enabling smooth and quick insertion of the endoscope to an  
14      intracavitory site of interest while lessening pains on the part of the  
15      patient.

16           The signal light beam which is projected from the light source 3  
17      contains wavelength bands  $\lambda_1$  to  $\lambda_n$ . As shown in Fig. 8, the signal  
18      light is divided into four light fluxes at the source light flux divider 20  
19      and the respective light fluxes are passed through a beam splitter 21

1 and separately fed to light input ends of the FBG strands 1a to 1d. As  
2 a result, reflection diffraction light signals of wavelengths  $\lambda_1, \lambda_2, \lambda_3,$   
3 ....  $\lambda_n$  come out from the refractive index change sections 2a, 2b, 2c, ...  
4 2n within the respective FBG strands 1a to 1d. These returned  
5 reflection diffraction light signals are reflected off the beam splitters 21  
6 and shed on the reflection light receiver 22. At the reflection light  
7 receiver, reflection diffraction light signals from refractive index change  
8 sections 2a to 2n in each one of the FBG strands 1a to 1d are  
9 sequentially taken in, for example, by the use of a switching means.

10 The thus obtained signals of reflection diffraction light from the  
11 FBG strands 1a to 1d are each checked for spectral distribution by  
12 spectroscopic analysis. In this regard, shown by solid line in Fig. 9is  
13 the spectrum of reflection diffraction light from a reference refractive  
14 index change section which is free of distortions or strains by bending.  
15 Indicated by one-dot chain line in the same figure is the spectrum of  
16 reflection diffraction light from a refractive index change section which  
17 is in a bent state. Therefore, a peak value of each reflection diffraction  
18 signal is detected at a spectrum analyzer 24 to determine a difference  
19 from a reference wavelength, that is to say, to determine the amount of

1 shift of each reflection diffraction signal. If there is no shift in the  
2 wavelength of the reflection diffraction light, in other words, if it is  
3 substantially same as the wavelength of a reference reflection  
4 diffraction light signal, the FBG strands 1a to 1d are considered in a  
5 rectilinear state. If there is a shift in wavelength, the sensor cable 5 is  
6 considered to be in a bent state. For example, in a case where there  
7 are positive (+) shifts in wavelengths of return signals from the FBG  
8 strands 1a and 1c and negative (-) shifts in wavelengths of return  
9 signals from the FBG strands 1b and 1d, it is considered that the  
10 refractive index change sections of the FBG strands 1a and 1c which  
11 are on the outer side of a bend are elongated while the refractive index  
12 change sections of FBG strands 1b and 1d which are on the inner side  
13 of a bend are shrunk. Besides, the radius of curvature varies  
14 correspondingly in relation with the amount of shift in wavelength.  
15 Namely, greater the amount of shift in wavelength, the smaller  
16 becomes the radius of curvature of a bend.

17 Now, in the case of the sensor cable 5, a three-dimensional  
18 coordinate system is formed as shown in Fig. 10, having X-, Y- and Z-  
19 axes represented by the FBG strands 1c and 1d, FBG strands 1a and

1        1b and the axial direction of the sensor cable 5, respectively. For  
2        displaying three-dimensional shapes of the sensor cable 5, values in  
3        direction and extent of bending of the sensor cable 5 are plotted on  
4        this three-dimensional coordinate system.

5              For this purpose, firstly amounts of shifts from a reference  
6        wavelength, which occurred to the refractive index change sections 2a  
7        to 2n of the FBG strands 1a and 1b, are computed at a radius of  
8        curvature computation circuitry 25 to determine radii of curvature of  
9        the refractive index change sections 2a to 2n. Further, radii of  
10        curvature of the refractive index change sections 2a to 2n of the FBG  
11        strands 1c and 1d are determined in a similar manner. In this  
12        instance, the interval between preceding and succeeding refractive  
13        index change sections in the sensor cable is P.

14              On the basis of the results of arithmetic operations by the radius  
15        of curvature computation circuitry 25, loci of the FBG strands 1a and  
16        1b in the direction of Z-axis and on a plane VF containing Y-axis are  
17        determined at a Y-axis flexure computation circuitry 26 from the radii  
18        of curvature of the refractive index change sections of the FBG strands  
19        1a and 1b and the interval P between the preceding and succeeding

1 refractive index change sections. Further, in a similar manner, loci of  
2 FBG strands 1c and 1d in the direction of z-axis and on a plane HF  
3 containing x-axis are determined from the radii of curvature of the  
4 refractive index change sections of the FBG strands 1c and 1d and the  
5 interval P between the preceding and succeeding refractive index  
6 change sections.

7 Then, the data from the y-axis flexure computation circuitry 26  
8 and the X-axis flexure computation circuitry 27 are processed into  
9 graphical data of a three-dimensional shape of the sensor cable 5 at a  
10 3D image processor circuitry 28. The obtained graphical data are of a  
11 three-dimensional shape of the sensor cable. However, since the  
12 sensor cable 5 is placed in a biopsy channel of the flexible insertion  
13 tube 12 of the endoscope 10, the three-dimensional shape of the  
14 sensor cable 5 can be deemed and displayed as a three-dimensional  
15 shape of the insertion tube 12.

16 Turning now to Fig. 11, there is shown a second embodiment of  
17 the present invention. In the case of this embodiment, all of the  
18 refractive index change sections 31 in a FBG strand 30 have the same  
19 refractive index. Accordingly, Bragg wavelength light, substantially

1 consisting of a single wavelength, is projected from a light source 32.  
2 The light from the light source 32 is divided into a signal light beam to  
3 be fed to the FBG strand 30 and a reference light beam. The signal  
4 light is fed to the FBG 30 through a beam splitter 34 which is located  
5 in the path of the signal light. As a result, return signals of reflection  
6 diffraction light are obtained from the respective refractive index  
7 change portions 31. These return signals of reflection diffraction light  
8 are reflected off the beam splitter 34 and projected on a wave surface  
9 synthesizing beam splitter 35.

10 On the other hand, the reference light beam, which has been  
11 divided by the half mirror 33, is reflected off a reflecting mirror 36 to  
12 turn its light path and fed to a variable length light path means 37 and  
13 then to the wave surface synthesizing beam splitter 35 after converting  
14 its direction of polarization through a half wave plate 38. In this  
15 instance, the variable length light path means 37 is provided with  
16 reflecting surfaces 37a and 37b which are disposed at the angle of 90  
17 degrees relative to each other, and can be moved in the direction of the  
18 arrow by a drive means which is not shown. Therefore, the length of  
19 the reference light path can be equalized with the length of light path

1 of the reflection diffraction light from the respective refractive index  
2 change portions 31. Instead of the above-described arrangement, the  
3 variable length light path means can be arranged by the use of a  
4 retroreflector or a right-angle type prism.

5 Thus, by the variable length light path means 37, the length of  
6 the reference light path is sequentially adjusted to match the lengths  
7 of reflection diffraction light paths from the respective refractive index  
8 change portions 31 of the FBG strand 30. At the wave surface  
9 synthesizing beam splitter (or an optical circulator) 35, the reflection  
10 diffraction light from the FBG 31 is transmitted and the reference light  
11 is reflected off. In synthesizing the two wave surfaces, interference  
12 occur therebetween. Images of interference fringes are taken by a  
13 camera 39 to detect the extent of bending flexure at each one of the  
14 refractive index change portions 31 on the basis of the information of  
15 interference fringes. Namely, the greater the extent of flexure, the  
16 smaller becomes the interference fringe signal. Accordingly, three-  
17 dimensional shapes of an elongated flexible member like the  
18 endoscopic insertion tube 12 can be measured by the use of a sensor  
19 cable with four FBG strands in a manner similar to the above-

1 described first embodiment of the invention. Besides, the degree of  
2 bending flexure at each refractive index change portion 31 can be  
3 detected on the basis of interference fringe information. Accordingly,  
4 in this case, there is no necessity for processing reflection diffraction  
5 light signals from four FBG strands for spectral analysis.
